Big news!

Detection of an Infectious Retrovirus, XMRV, in Blood Cells of Patients with Chronic Fatigue Syndrome

Vincent C. Lombardi,^{1*} Francis W. Ruscetti,^{2*} Jaydip Das Gupta,³ Max A. Pfost,¹ Kathryn S. Hagen,¹ Daniel L. Peterson,¹ Sandra K. Ruscetti,⁴ Rachel K. Bagni,⁵ Cari Petrow-Sadowski,⁶ Bert Gold,² Michael Dean,² Robert H. Silverman,³ Judy A. Mikovits^{1†}

Chronic fatigue syndrome (CFS) is a debilitating disease of unknown etiology that is estimated to affect 17 million people worldwide. Studying peripheral blood mononuclear cells (PBMCs) from CFS patients, we identified DNA from a human gammaretrovirus, xenotropic murine leukemia virus-related virus (XMRV), in 68 of 101 patients (67%) as compared to 8 of 218 (3.7%) healthy controls. Cell culture experiments revealed that patient-derived XMRV is infectious and that both cell-associated and cell-free transmission of the virus are possible. Secondary viral infections were established in uninfected primary lymphocytes and indicator cell lines after their exposure to activated PBMCs, B cells, T cells, or plasma derived from CFS patients. These findings raise the possibility that XMRV may be a contributing factor in the pathogenesis of CFS.

Chronic fatigue syndrome (CFS) is a disorder of unknown etiology that affects multiple organ systems in the body. Patients with CFS display abnormalities in immune sys-

tem function, often including chronic activation of the innate immune system and a deficiency in natural killer cell activity (1, 2). A number of viruses, including ubiquitous herpesviruses and

XMRV Expert Elicitation Workshop

*XMRV = Xenotropic murine leukemia virus-related virus
a gammaretrovirus first described in 2006*

Following calibration, the experts were asked to answer a number of target questions for which answers are unknown.

Work with McLaughlin Centre for Population Health Risk Assessment, Univ. Ottawa

Target Question 1

A set of target questions that asked about the current prevalence of XMRV infection in the world (1), Canada (3), USA (4), UK (5) and France (6) in the general adult population? (1 in xxxxx)

Performance Weighted Solution:

- Median: 1 in 126
- Range: 1.2-452,300

Target Question 31

What percentage of infected XMRV carriers are asymptomatic?

Expert Weighted:

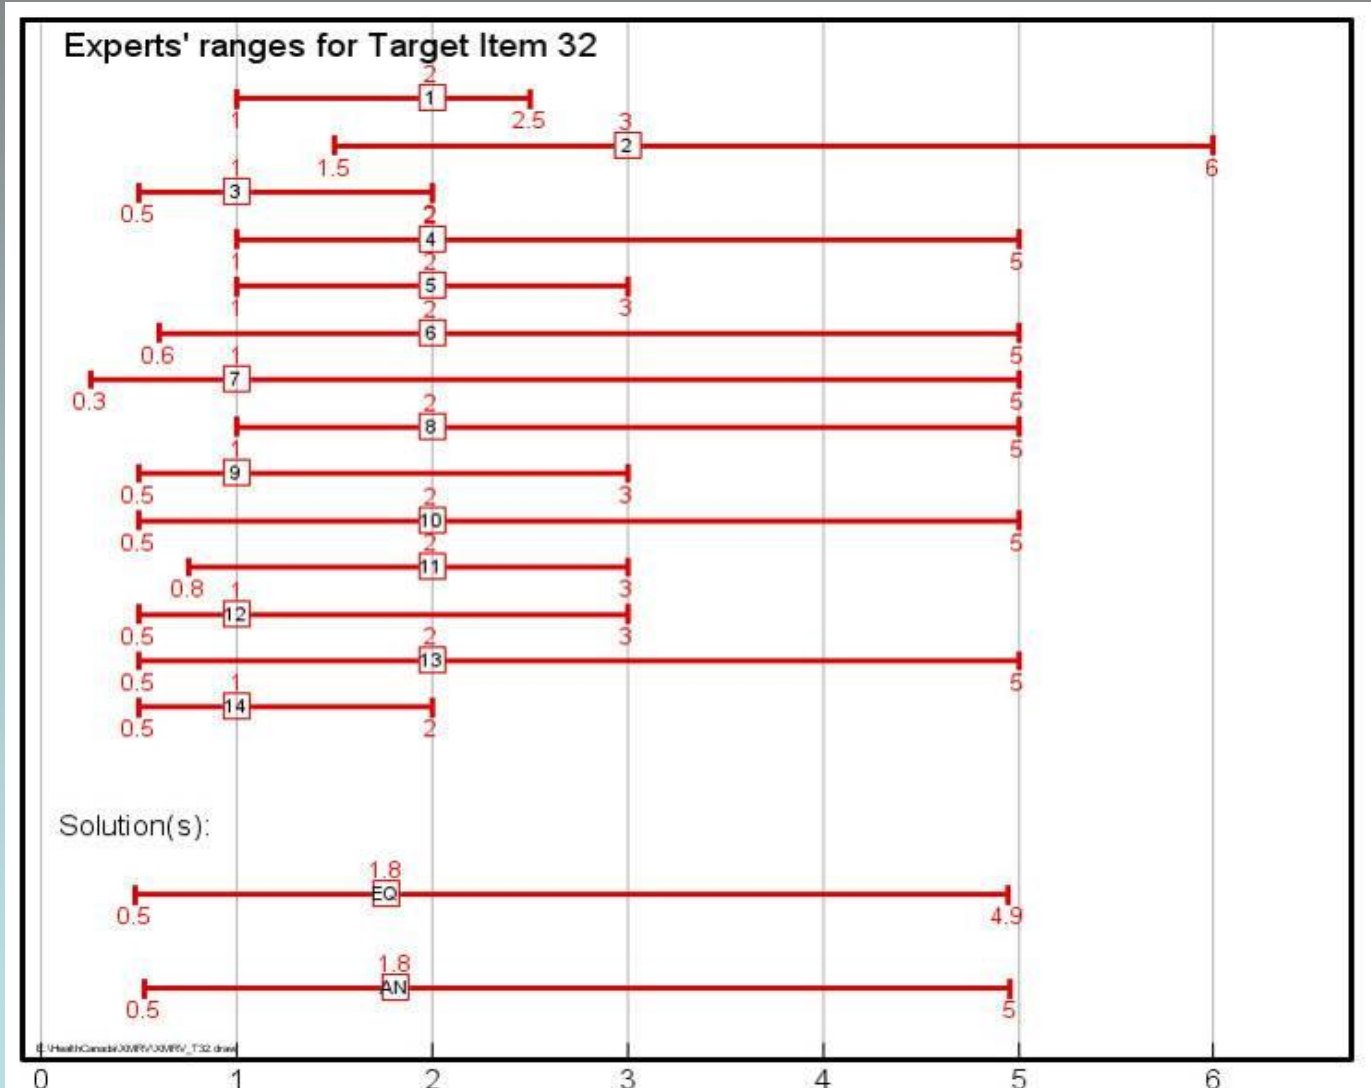

- 92.7 %
- Range: 64.4-98.9

Experts believe the majority of XMRV infections are asymptomatic.

Short right tails suggest experts are more certain that the value is higher than lower.

Target Question 32

When will the data be available to generate testing/ screening of blood donors for XMRV?

Expert Weighted:

- 1.8 years
- Range: 0.5-5.0

Experts best estimate for available data and improved techniques for XMRV testing is within 2 years (left tailed skew).

Eventual outcome ...

REPORTS

No Evidence of Murine Gamma Retrovirus in Blood of Patients with Chronic Fatigue Syndrome

Konstance Knox
John Hackett Jr.
Andreas M. Kogut

Members of the XMRV [xenotropic murine leukemia virus-related virus] panel present in the blood of 61 patients identified as XMRV transcription positive for detection of other MLVs in the blood of strongly (X-MLV) and healthy controls would be unlikely to be detected in a laboratory reagent panel. CFS is likely attributed to

Xenotropic murine leukemia virus-related virus (XMRV) in mice, and the possibility of being integrated into the genome is able to reinfect cells as the name (xenotropic murine leukemia virus-related virus)

Retraction

MEDICAL SCIENCES

Retraction for "Detection of MLV-related virus gene sequences in blood of patients with chronic fatigue syndrome and healthy blood donors," by Shyh-Ching Lo, Natalia Pripuzova, Bingjie Li, Anthony L. Komaroff, Guo-Chiuan Hung, Richard Wang, and Harvey J. Alter, which appeared in issue 36, September 7, 2010, of *Proc Natl Acad Sci USA* (107:15874–15879; first published August 23, 2010; 10.1073/pnas.1006901107).

The authors wish to note the following: "Although our published findings were reproducible in our laboratory and while there has been no evidence of contamination using sensitive mouse mitochondrial DNA or IAP assays or in testing coded panels, we have the following concerns:

1. The original chronic fatigue syndrome (CFS) patient samples were of insufficient volume to distribute to other laboratories for independent confirmation.
2. Only one (1) of many laboratories has found a similar association between polytropic murine leukemia viruses (pMLV) and CFS and a careful study of 100 CFS patients (2), as well as a coded panel recently constructed by the National Heart, Lung, and Blood Institute (NHLBI) (3), have found no evidence for either xenotropic murine leukemia virus-related virus (XMRV) or pMLVs in CFS patient samples.
3. Our attempts, through collaborations, to demonstrate antibody in affected patients, to isolate the virus by culture, or to show integration sites in the human genome have failed to support the initial findings.
4. While recall of eight patients from the original cohort 15 y later showed pMLV gag sequences in seven, the copy number was very low and phylogenetic analysis showed these sequences were not direct descendants of the original dominant strains (4). Still later samples from four of these pa-

tients tested negative in the NHLBI panel. While this result could be explained by viral clearance over time, it fails to support a sustained retroviral infection in human cells.

Although a more definitive, National Institute of Allergy and Infectious Diseases (NIAID)-sponsored, coded panel of samples from 150 well-characterized and geographically diverse CFS patients and controls is being assembled for further study, in consideration of the aggregate data from our own laboratory and that of others, it is our current view that the association of murine gamma retroviruses with CFS has not withstood the test of time or of independent verification and that this association is now tenuous. Therefore, we retract the conclusions in our article."

OPINION

A route to more tractable expert advice

There are mathematically advanced ways to weigh and pool scientific advice. They should be used more to quantify uncertainty and improve decision-making, says **Willy Aspinall**.

When a volcano became restless on the small, populated island of Montserrat, West Indies, in 1995, there was debate among scientists: did the bursts of steam and ash presage an explosive and deadly eruption, or would the outcome be more benign? Authorities on the island, a British overseas territory, needed advice to determine warning levels, and whether travel restrictions and evacuations were needed. The British government asked me, as an independent volcanologist, to help reconcile differing views within the group.

As it happened, I had experience not only with the region's volcanoes, but also with a unique way of compiling scientific advice in the face of uncertainty: the Cooke method of 'expert elicitation'. This method weighs the opinion of each expert on the basis of his or

to remove it from the decision process.

Of the many ways of gathering advice from experts, the Cooke method is, in my view, the most effective when data are sparse, unreliable or unobtainable.

Rational consensus

Advice during an emergency is usually the responsibility of a chief scientist, with all the stresses that involves — including the pressure to be extremely cautious. There is a better way: pooling the opinions of a group of specialists.

There are several methods of such expert elicitation, each with flaws. The traditional committee still rules in many areas — a slow, deliberative process that gathers a wide range of opinions. This has parallels with the scientific process itself. But committees traditionally give all experts equal weight (one person, one

the Delft University of Technology in the Netherlands with his colleagues, instead produces a 'rational consensus'. To see how this works, take as an example an elicitation I conducted in 2003, to estimate the strength of the thousands of small, old earth dams in the United Kingdom. Acting as facilitator, I first organized a discussion between a group of selected experts about how water can leak into the cores of such ageing dams, leading to failure. The experts were then asked individually to give their own opinion of the time-to-failure in a specific type of dam, once such leakage starts. They answered with both a best estimate and a 'credible interval', for which they thought there was only a 10% chance that the true answer was higher or lower.

I also asked each expert a set of eleven 'seed questions', for which answers are known, so

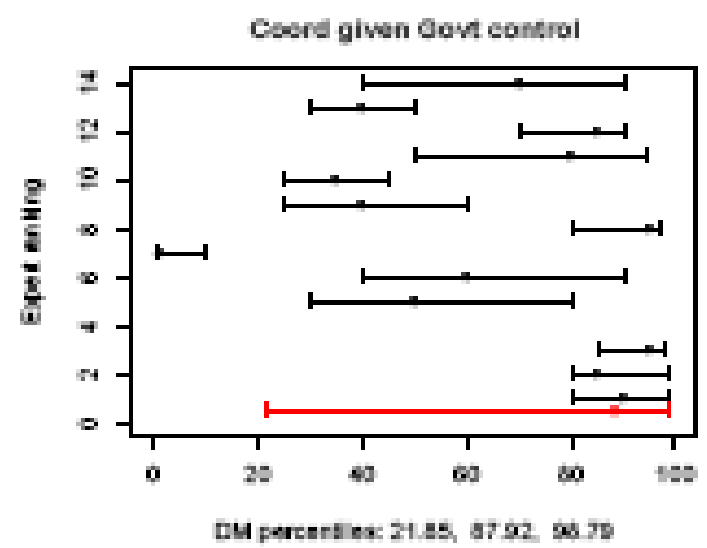

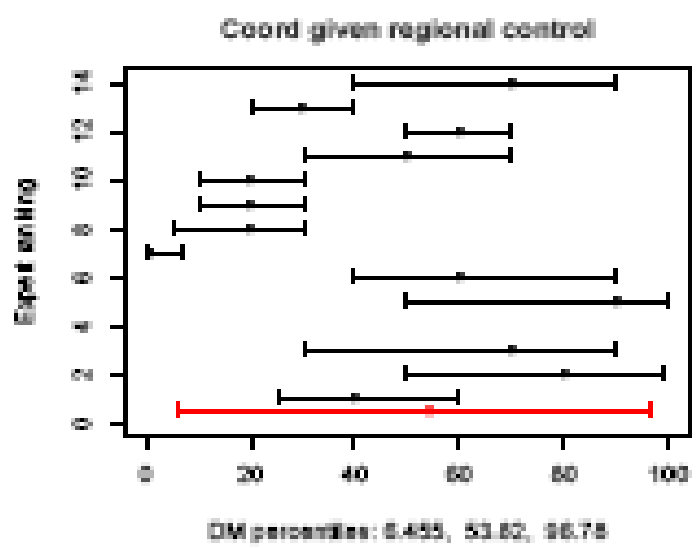

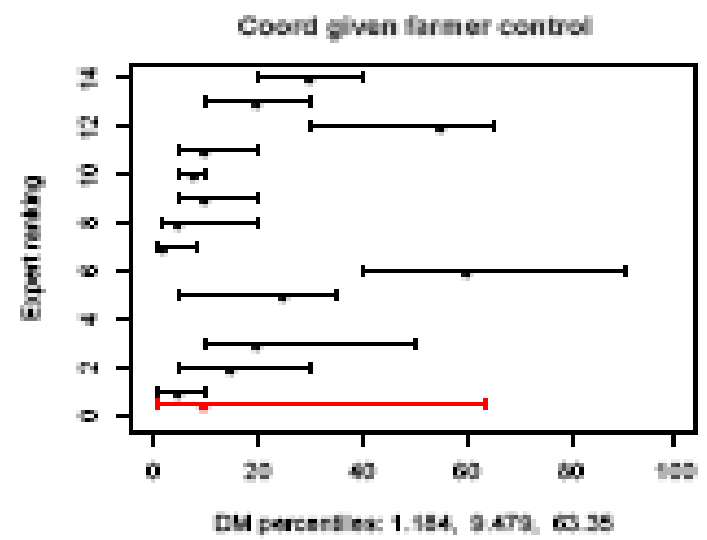

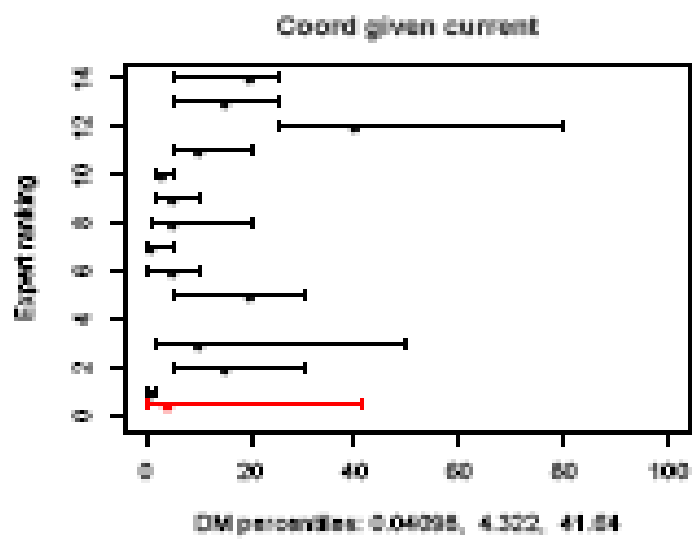

.... and apply them to scabby sheep:

AD79 eruption: plaster casts of victims who were burnt to death are now a tourist attraction

Vesuvius blast could kill 300,000

■ John Follain

THE next eruption of Vesuvius could kill at least 300,000 people, nearly 20 times as many as the AD79 disaster that buried the ancient city of Pompeii, according to Italian government research.

More than half a million people live in the so-called "red zone" of 18 towns in a four-mile radius of the volcano and most would die if an evacuation could not be completed in time, the research says.

The findings are from a study by some of Europe's leading volcanologists and public health experts, including Dr Peter Baxter of Cambridge University's Department of Public Health.

The destruction of Pompeii, the worst affected city, has inspired many books and films, including Robert Harris's 2003 bestseller, which features Pliny the Elder and which is to be adapted by the director Roman Polanski in a £100m movie. Some 2.5m tourists visited Pompeii last year, where the

people by bus from each of the 18 towns. Professor Giuseppe Luongo of the University of Naples, a former director of the Vesuvius Observatory which monitors the volcano, believes plans are inadequate and local people are ill-informed about them.

escape," he said. "We need a plan for the evacuation of vulnerable people, like pensioners, fast. People need to know what to do and they have to understand they won't be able to get out by car. You can walk 10 miles in three hours, that's quite a good safety margin." Some Neapitans are hoping Vesuvius will stir soon. Guides who work near its summit believe a volcano that splatters, groes and occasionally spits fire and lava is a better crowd-puller than a dull, tepid one who only to describe the weather.

Expert elicitations

Vesuvius last awoke with a small blast in 1944. A large eruption could unleash incendiary avalanches and ash that would threaten millions of people.

EUROPE'S TICKING TIME BOMB

Vesuvius is one of the most dangerous volcanoes in the world — but scientists and the civil authorities can't agree on how to prepare for a future eruption.

It starts with a blast so strong that a column of ash and stone rockets 40 kilometres up into the stratosphere. The debris then drops to Earth, pelting the surface with boiling hot fragments of pumice and covering the ground with a thick layer of ash. Roofs crumble and...

The legal aftershocks of the earthquake in L'Aquila

Science is in the dock in Italy as local witnesses finally confront the earthquake on trial for manslaughter who, it is alleged, failed to warn them of the risks.

A formula for justice

Bayes' theorem is a mathematical equation used in court cases to analyse statistical evidence. But a judge has ruled it can no longer be used. Will it result in more miscarriages of justice?

Ice sheet melting – projected contributions to future sea-level rise

An expert judgement assessment of future sea level rise from the ice sheets

J. L. Bamber^{1*} and W. P. Aspinall²

A major gap in predictive capability concerning the future evolution of the ice sheets was identified in the Fourth Assessment Report (AR4) of the Intergovernmental Panel on Climate Change. As a consequence, it has been suggested that the AR4 estimates of future sea-level rise from this source may have been underestimated. Various approaches for addressing this problem have been tried, including semi-empirical models and conceptual studies. Here, we report a formalized pooling of expert views on uncertainties in future ice-sheet contributions using a structured elicitation approach. We find that the median estimate of such contributions is 29 cm—substantially larger than in the AR4—while the upper 95th percentile value is 84 cm, implying a conceivable risk of a sea-level rise of greater than a metre by 2100. On the critical question of whether recent ice-sheet behaviour is due to variability in the ice sheet-climate system or reflects a long-term trend, expert opinion is shown to be both very uncertain and undecided.
